

# DIGITAL PHOTOGRAPHY

: KELVIN AITKEN ©2007 www.marinethemes.com

HAVE YOU EVER HAD A PROBLEM WITH AN ELECTRONIC DEVICE, MANY MONTHS/YEARS AFTER YOUR PURCHASE, AND HAVE TORN YOUR HAIR OUT TRYING TO FIND THE MANUAL? OR JUMPED INTO YOUR CAR AND REACHED FOR YOUR TRUSTY ROAD MAP, ONLY TO FIND THAT IT'S MISSING? HAD TO JOT DOWN A PHONE NUMBER AND THE PEN IS MISSING? FRUSTRATING? NOW IMAGINE THAT YOU ARE ONE OF THOSE SUPER-ORGANISED TYPES. YOUR MICROWAVE MANUAL IS TAPED TO THE BACK OF THE UNIT, YOUR PHONE PEN IS CHAINED TO THE PHONE AND YOUR CAR MAP IS STORED IN AN ON-BOARD COMPUTER. I HATE THOSE SORTS OF PEOPLE.

**W**ell the same can happen to your digital image files. Sure, your last dive, dive #100, was memorable because it was the first dive on a famous wreck, you cracked the century in your dive log and the weather was perfect. So perhaps in a couple of years time you can identify the photos from dive #100 – but what about dive 109, or dive 52? Or where did you find that particular weird scorpionfish? Where was it taken? What exposure did I give that? What lens did I use?

A few issues back we discussed creating a database to keep track of your hundreds, thousands and tens of thousands of digital image files. It can be very satisfying to look through last weekend's photos and fiddle with them, maybe print some out, transfer some to your phone, make a desktop image for your computer, email a few braggable goodies to your friends at work. When you're doing that, entering the relevant information into your database is a logical thing to do. But what if your photo and your database get separated? How can you ensure that your caption information is matched to your images? How can you find out the date, time, exposure, lens used, etc?

Metadata is your answer. What is it? Metadata is information stored within your image file. It gets there in two ways. First, your

**K**elvin Aitken is a Melbourne-based professional photographer and diver passionate about the big blue and the big sea creatures to be found out there. He's dived from the Arctic to the extremes of the South Pacific

and if there's a new marine dive adventure to be experienced or invented, he's always the first to put up his hand. He's also dived the southeastern Australian continental shelf and photographed shark species nobody knew would be found out there. Kelvin is a BBC Wildlife Photographer of the Year marine category winner and his unique work is on [www.marinethemes.com](http://www.marinethemes.com)

digital camera inserts metadata into the image file. That type of metadata is called Exchangeable Image File Format or EXIF data. The second type of metadata is information that you add yourself. This is called IPTC, short for International Press Telecommunications Council. They, the Tele Council, created IPTC data as a means to keep track of images by including captions and other information with an image. So, if you 'found' an image and wanted to use it in a news story, you could check to see if it was copyright-protected, who the author was, plus other information added by the photographer such as where and when the photo was taken and possibly a caption describing the image or the events portrayed in the image.

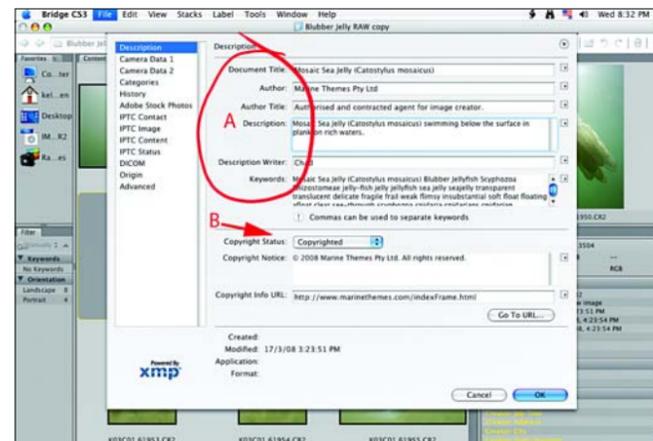

IPTC metadata obviously has more uses than those unique to newspapers. Other publishers and stock photo libraries use IPTC metadata as a way to keep important information with the image file or to 'suck' information out of the file to insert into image databases. Those clever folks at Adobe, makers of Elements and Photoshop, took the IPTC system and incorporated it into a new system called XMP, Extensible Markup Platform. This does much the same job but is able to be shared with software developers to incorporate it in many different software applications and file types. You can even convert a file from one format, such as TIFF, into another format, such as JPEG, and retain the metadata.

So how do you get your information inside the image file? One way is to use your photo editing software. Photoshop, Elements and your camera's RAW file converter let you add metadata information. In Photoshop or Elements, go to File>File Info and up pops a dialogue box which allows you to add captions, keywords, copyright information and more. Elements gives you fewer options than Photoshop but those options are more than adequate for most needs. These include an image title, author's name, caption, copyright status, copyright notice and a URL or web page (or email address) to contact the owner. You don't need to strictly add just those pieces of information; you can add anything you want in there but it's best to follow the general theme of things to avoid problems further down the line. For example, if you were to put information about the photo in the URL field you won't break anything, but that information field would generally be ignored by a database

importing information just from the captions field. A stock photo library would, for example, ignore the URL field because they already know who you are and are not interested in copying contact information that we can assume they already have.

As a matter of interest, Elements and Photoshop or similar programs also will show you the EXIF information. This info is mostly uneditable because it is a record of fact, not a record of added information. It lists, among other things, the camera model, exposure time or shutter speed, f-stop used, ISO speed rating, date shot, etc. It will also show some of the IPTC info that you can edit such as Image Description and Artist. Because most of this information is uneditable, you can find out the origins or original camera information. So if you enter a photo competition which stipulates that images must have been taken during a particular time period, they can check the creation date of your digital camera files.

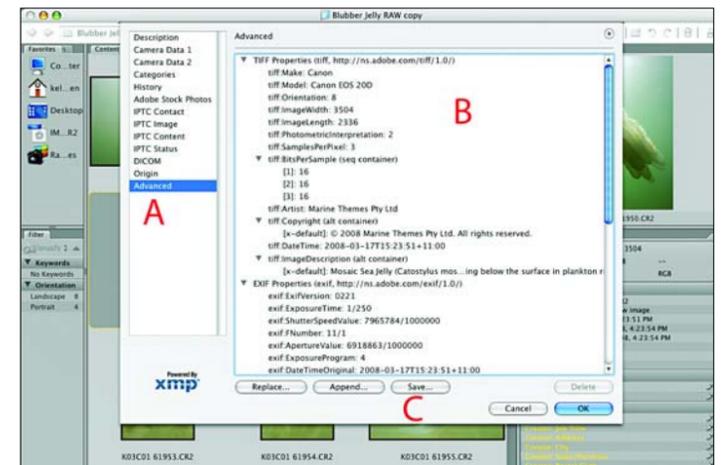

So there you sit, with a few folders holding 300 images from your last weekend dive trip to a shipwreck off the coast. Obviously there are pieces of information that will be common to all images, such as the name of the shipwreck and it's location, the author (you), the fact that it's a copyrighted work with an appropriate copyright notice and your Owner URL. In addition, you may have other information that varies, such as the caption. So let's say you have

Using my RAW file converter, in this case Adobe Bridge which is part of the Photoshop package, I've opened the File Info dialogue box and filled the Description fields (A) with my own information. I've changed the Copyright Status (B) from Unknown to Copyrighted and filled in a copyright notice and a copyright URL. All of this information now becomes part of the image file.

300 shots taken on your weekend jaunt to the HMAS *Sydney* off the West Australian coast. OK, no chance of that but you can dream. You have two fields that will take all of the variable information, the Title field and the Caption field. So the title could be 'HMAS *Sydney* shipwreck' and the caption could be 'HMAS *Sydney* shipwreck. Detail of the skeleton holding the box of gold coins and pirate jewels.' The next image would have the same title but the caption may be slightly different or completely different. Such as 'Davo wearing the emerald and diamond encrusted crown on the bow of the HMAS *Sydney* shipwreck with giant squid stalking him.'

From the above example we can automate the process of adding the same title along with copyright information to every image file but we'll need to customise or change the caption information. You can do this using Photoshop or Bridge (the Adobe file browser software which comes with Photoshop 8 and above) or another software application designed for this purpose. Elements lets you add or change metadata information but doesn't let you batch process images or save metadata templates. This may have changed in recent versions. Check your Elements Help file using the 'File Info' search term.

After filling in the Description fields, and any of the others that I care to fill in, I click the Advanced tab (A) which allows me to view various types of metadata (B). This tells me that the image I am working on was shot on a Canon 20D, it is a 16 bit image file, some of my Description IPTC information has been included, the date and time of the image capture is shown and exposure information is shown in the EXIF properties list. With Bridge I have to access the Advanced tab to save the metadata (C) as an XMP file so that it can be applied to any other image that has the same general information.
